INTRODUCTION Lack of insight is a key factor in psychotic psychopathology both for its implications and for its frequency. Most researches on the subject, have been conducted in western countries neglecting the influence of socio-cultural aspects in its study. **OBJECTIVE** We aim to determine how cultural factors modulate the capacity of insight in immigrants affected by a first psychosis episode compared to western patients. **MATERIAL AND METHODS** We compared insight grade evaluated with Beck Cognitive Insight Scale in two immigrant groups (Western and Non-Western) affected by a first episode psychosis according to clinical feature and severity of symptoms measured by Positive and Negative Syndrome Scale (PANSS). **RESULTS** We observed statistically significant differences in insight grade between Western and Non-Western groups ($p = 0.019$). The Western group obtained higher scores in the Self-reflectiveness subscale (R) ($p = 0.05$) and in the Composite Index (R-C) ($p = 0.013$) whereas the mean in the Self-Certainty subscale (C) ($p = 0.123$) was higher in the Non-Western population. Insight grade adjusted by PANSS performance was also examined, showing a statistically significant ($r = -0.198$) inverse relationship. **CONCLUSIONS** We believe that cultural perspective should systematically be considered in the evaluation of all patients diagnosed with first episode psychosis and particularly in the evaluation of insight.
