

# Abuso sexual infantil en la génesis de los problemas psicopatológicos en la edad adulta: caso clínico [

2021

text (article)

Analítica

It is estimated that about 10% - 20% of the world's population has experienced child sexual abuse (CSA). The CSA has been related to short- and long-term consequences depending on the abusive experience and characteristics of the victim. The most documented consequences of ASI, include PTSD, mood and personality disorders, anxiety, somatic and sexual problems, and the risk of revictimization. The aims of this study were a) to analyze the psychopathology associated with CSA in a 45-yearold woman who suffered maintained childhood sexual abuse and different experiences of revictimization throughout her life. b) The magnitude of the therapeutic change after a CognitiveBehavioural treatment focused on trauma. Treatment efficacy was measured through the percentage of nonoverlapping data (PND), the data exceeding the mean (PEM) and the non-overlap of all pairs (NAP). The results allowed to describe the consequences and pathology of CSA and corroborated the therapeutic change on the CSA survivor
