Analítica

Three cohorts of undergraduate psychology theses ($n = 57$) performed by last year undergraduate psychology students from Universidad Católica Andrés Bello, were monitored using 5 longitudinal measurements of progression. A Generalized Additive Model, to predict the completion time of the theses, is tested against two completion times: early and delayed. Effect size measures favor a multiple dimension model over a global progress model. The trajectory of the indicators through the 5 measurements allows the differentiation between early and delayed completion. The completion probabilities estimated by the dimensional model allow the identification of differential oscillation levels for the distinct completion times. The initial progression indicators allow the prediction of early completion with a 71% success rate, while the final measurement shows a success rate of 89%. The results support the effectiveness of the supervisory system and the analysis of the progression dynamics of the theses from a task-delay model, focused on the relationship between the amount of task completion and the deadlines
