

Conducta sexual y reproductiva durante la adolescencia de los estudiantes de la Universidad Mayor de San Simón [

2019

text (article)

Analítica

Objectives: to analyze factors related to sexual risk behavior during the adolescence of students at the San Simón University, management 2018. **Methods:** retrospective cohort study, sampling was non-probability with inclusion and exclusion criteria. A self-administered survey was applied in 4 different sites of the university. The analysis of the data was carried out with the program Epi-info v.7.2, using uni and bivariate analysis, as association measures OR, chi2 with a significant p value less than or equal to 0.05. **Results:** the proportion of participants who began their active sexual life during adolescence was 50%, of whom 31% do not use any contraceptive method and 69% if they use any method of contraception, of whom 46% prefer to use the male condom or the morning-after pill. A significant relationship of early sexual debut (before age 16) was found with the variables: being male, coming from a dysfunctional family, little access to sources of information about sexuality, consumption of psychoactive substances before sexual intercourse, and having had an informal or casual sexual partner. **Conclusions:** adequate sexual behavior in the adolescent depends to a large extent on a functional family environment and adequate access to information on sexuality and reproduction. The prevention of unwanted pregnancies and sexually transmitted infections in adolescents must also focus on the adolescent's family environment and society
