

Abordaje "Degloving" del tercio medio de la cara en el tratamiento de tumores [

2010

text (article)

Analítica

"Degloving" is an "endobucal" an "endonasal" surgical technique of the middle third of the face which allows an ample, asymmetrical and bilateral exposure of the nasal cavity, paranasal sinuses. Without making skinscars. This is complemented with osteotomies (bone rearrangement) so we can reach the base of the skull and to resect tumours located in this region. We describe the surgical technique used in 56 patients admitted to the E.R hospital, because benign and malignant tumours of the head and neck. Endoscopy, helical CT and for MRI gave us the precise and exact location of these group of tumours distributed in the nasal cavity, paranasal sinuses, rhinopharynx and the skull base. The good results obtained functionally as well as cosmetically, were assessed by the attending surgeons and for the patients and their relatives involved. The low incidence of sequelae and complications allow us to recommend this surgical technique as an important therapeutic option in the management of middle third and of the skull pathology.
